

## VEHICLE SPEED CONTROL SYSTEM

### BACKGROUND OF THE INVENTION

The present invention relates to a vehicle speed control system for controlling a vehicle speed, and more particularly to a control system which controls a vehicle so as to automatically cruise at a set vehicle speed.

Japanese Patent Provisional Publication No. (Heisei) 11-314537 discloses a vehicle speed control system which controls a vehicle speed so that an actual lateral acceleration of the vehicle does not become greater than a preset lateral acceleration.

### SUMMARY OF THE INVENTION

This control system is arranged to decelerate the vehicle from a target vehicle speed at a predetermined vehicle-speed variation (acceleration/deceleration) which maintains the actual lateral acceleration below a preset value. However, when the preset value of the deceleration (acceleration) is set at a small value adapted to a high speed traveling and when the vehicle travels at a low vehicle speed, the vehicle stability is degraded due to the vehicle motion characteristics under a low speed traveling condition. More specifically, since the natural frequency of a lateral motion of the vehicle is high under a low speed traveling condition, that is, since a steering response of the vehicle is quick under the low speed traveling condition, the lateral acceleration of the vehicle tends to become large and therefore the vehicle stability tends to be degraded. On the other hand, when the preset value of the deceleration (acceleration) is set at a large value

adapted to a low speed traveling and when the vehicle travels at a high vehicle speed, the large deceleration of the vehicle impresses a strange feeling to a driver.

5       It is therefore an object of the present invention to provide an improved vehicle speed control system which ensures a vehicle stability during the deceleration of the vehicle without impressing a strange feeling to a driver even if the  
10       vehicle travels at any vehicle speed.

      Another object of the present invention is to provide a vehicle speed control system which can decides whether the vehicle is traveling a curved road and varies the variation  
15       (acceleration/deceleration) of a command vehicle speed so as to fit with a drive feeling during a constant vehicle speed cruise control.

      A vehicle speed control system according to the present invention is for a vehicle and comprises a  
20       lateral acceleration sensor which senses a lateral acceleration of the vehicle, a vehicle speed sensor which senses a vehicle speed of the vehicle, a target vehicle speed setting device for setting a target vehicle speed, a drive system which generates  
25       drive force of the vehicle, and a controller connected with the lateral acceleration sensor, the vehicle speed sensor, the target vehicle speed setting device and the drive system. The controller is arranged to calculate a correction quantity based  
30       on the lateral acceleration and the vehicle speed to calculate a command vehicle speed on the basis of the vehicle speed, the target vehicle speed, a variation of the command vehicle speed, and the

correction quantity, and to control the drive system to bring the vehicle speed closer to the command vehicles speed.

In addition to the above aspect, the controller according to the present invention may be further arranged to determine whether the vehicle is traveling on a curved road, and to determine the variation of the command vehicle speed at the time after the traveling on the curved road is terminated, on the basis of one of a curve-terminated vehicle speed at the time when the curved road traveling is terminated and a start-end deviation between the vehicle speed at the time when the vehicle starts traveling on a curved road and the vehicle speed at the time when the curved road traveling is terminated.

#### BRIEF DESCRIPTION OF THE DRAWINGS

Fig. 1 is a block diagram showing a structure of a vehicle speed control system according to the present invention.

Fig. 2 is a block diagram showing a structure of a lateral-acceleration vehicle-speed correction-quantity calculating block 580.

Fig. 3 is a graph showing a relationship between a vehicle speed  $V_A(t)$  and a cutoff frequency  $f_c$  of a low pass filter.

Fig. 4 is a graph showing a relationship between a correction coefficient  $CC$  for calculating a vehicle speed correction quantity  $V_{SUB}(t)$  and a value  $Y_G(t)$  of the lateral acceleration.

Fig. 5 is a graph showing a relationship between a natural frequency  $\omega_{nSTR}$  and the vehicle speed.

Fig. 6 is a graph showing a relationship between an absolute value of a deviation between vehicle speed  $V_A(t)$  and a maximum value  $V_{SMAX}$  of a command vehicle speed, and a command vehicle speed variation  $\Delta V_{COM}(t)$ .

#### DETAILED DESCRIPTION OF THE INVENTION

Referring to Figs. 1 to 12, there is shown a vehicle speed control system according to an embodiment of the present invention.

Fig. 1 shows a block diagram showing a construction of the vehicle speed control system according to the embodiment of the present invention. With reference to Figs. 1 to 12, the construction and operation of the vehicle speed control system according to the present invention will be discussed hereinafter.

The vehicle speed control system according to the present invention is equipped on a vehicle and is put in a standby mode in a manner that a vehicle occupant manually switches on a system switch (not shown) of the speed control system. Under this standby mode, when a set switch 20 is switched on,

the speed control system starts operations.

The vehicle speed control system comprises a vehicle speed control block 500 which is constituted by a microcomputer and peripheral devices. Blocks  
5 in vehicle speed control block 500 represent operations executed by this microcomputer. Vehicle speed control block 500 receives signals from a steer angle sensor 100, a vehicle speed sensor 10, the set switch 20, a coast switch 30, an accelerate  
10 (ACC) switch 40, an engine speed sensor 80, an accelerator pedal sensor 90 and a continuously variable transmission (CVT) 70. According to the signals received, vehicle speed control block 500 calculates various command values and outputs these  
15 command values to CVT 70, a brake actuator 50 and a throttle actuator 60 of the vehicle, respectively, to control an actual vehicle speed at a target vehicle speed.

A command vehicle speed determining block 510  
20 of vehicle speed control section 500 calculates a command vehicle speed  $V_{COM}(t)$  by each control cycle, such as by 10ms. A suffix (t) denotes that the value with the suffix (t) is a value at the time t and is varied in time series (time elapse). In some  
25 graphs, such suffix (t) is facilitated.

A command vehicle speed maximum value setting block 520 sets a vehicle speed  $V_A(t)$  as a command vehicle speed maximum value  $V_{SMAX}$  (target speed) at time when set switch 30 is switched on. Vehicle  
30 speed  $V_A(t)$  is an actual vehicle speed which is detected from a rotation speed of a tire rotation speed by means of a vehicle speed sensor 10.

After command vehicle speed maximum value  $V_{SMAX}$

is set by the operation of set switch 20, command vehicle speed setting block 520 decreases command vehicle speed maximum value  $V_{SMAX}$  by 5km/h in reply to one push of coast switch 30. That is, when coast switch 30 is pushed a number  $n$  of times ( $n$  times), command vehicle speed  $V_{SMAX}$  is decreased by  $n \times 5\text{km/h}$ . Further, when coast switch 30 has been pushed for a time period  $T$  (sec.), command vehicle speed  $V_{SMAX}$  is decreased by a value  $T/1(\text{sec.}) \times 5\text{km/h}$ .

Similarly, after command vehicle speed maximum value  $V_{SMAX}$  is set by the operation of set switch 20, command vehicle speed setting block 520 increases command vehicle speed maximum value  $V_{SMAX}$  by 5km/h in reply to one push of ACC switch 40. That is, when ACC switch 40 is pushed a number  $n$  of times ( $n$  times), command vehicle speed maximum value  $V_{SMAX}$  is increased by  $n \times 5\text{km/h}$ . Further, ACC switch 40 has been pushed for a time period  $T$  (sec.), command vehicle speed maximum value  $V_{SMAX}$  is increased by a value  $T/1(\text{sec.}) \times 5(\text{km/h})$ .

A lateral acceleration (lateral  $G$ ) vehicle-speed correction-quantity calculating block 580 receives a steer angle  $\theta(t)$  from steer angle sensor 100 and vehicle speed  $V_A(t)$  from vehicle speed sensor 10, and calculates a vehicle speed correction quantity  $V_{SUB}(t)$  which is employed to correct the command vehicle speed  $V_{COM}(t)$  according to a lateral acceleration (hereinafter, it called a lateral- $G$ ). More specifically, lateral- $G$  vehicle-speed correction-quantity calculating section 580 comprises a steer angle signal low-pass filter (hereinafter, it called a steer angle signal LPF block) 581, a lateral- $G$  calculating block 582 and a

vehicle speed correction quantity calculation map 583, as shown in Fig. 2.

Steer angle signal LPF block 581 receives vehicle speed  $V_A(t)$  and steer angle  $\theta(t)$  and  
5 calculates a steer angle LPF value  $\theta_{LPF}(t)$ . Steer angle LPF value  $\theta_{LPF}(t)$  is represented by the following equation (1).

$$\theta_{LPF}(t) = \theta(t) / (TSTR \cdot s + 1) \quad \text{---(1)}$$

In this equation (1),  $s$  is a differential operator,  
10 and TSTR is a time constant of the low-pass filter (LPF) and is represented by  $TSTR = 1 / (2\pi \cdot fc)$ . Further,  $fc$  is a cutoff frequency of LPF and is determined according to vehicle speed  $V_A(t)$  as shown by a map showing a relationship between cutoff  
15 frequency  $fc$  and vehicle speed  $V_A(t)$  in Fig. 3. As is clear from the map of Fig. 3, cutoff frequency  $fc$  becomes smaller as the vehicle speed becomes higher. For example, a cutoff frequency at the vehicle speed  
20 100km/h is smaller than that at the vehicle speed 50km/h.

Lateral-G calculating block 582 receives steer angle LPF value  $\theta_{LPF}(t)$  and vehicle speed  $V_A(t)$  and calculates the lateral-G  $Y_G(t)$  from the following equation (2).

$$25 \quad Y_G(t) = \{V_A(t)^2 \cdot \theta_{LPF}(t)\} / \{N \cdot W \cdot [1 + A \cdot V_A(t)^2]\} \quad \text{---(2)}$$

In this equation (2),  $W$  is a wheelbase dimension of the vehicle,  $N$  is a steering gear ratio, and  $A$  is a stability factor. The equation (2) is employed in  
30 case that the lateral G of the vehicle is obtained from the steer angle.

When the lateral G is obtained by using a

yaw-rate sensor and processing the yaw rate  $\psi(t)$  by means of a low-pass filter (LPF), the lateral-G  $Y_G(t)$  is obtained from the following equations (3) and (4).

$$Y_G(t) = V_A(t) \cdot \psi_{LPF} \quad \text{---(3)}$$

5  $\psi_{LPF} = \psi(t) / (T_{YAW} \cdot s + 1) \quad \text{---(4)}$

In the equation (4),  $T_{YAW}$  is a time constant of the low-pass filter. The time constant  $T_{YAW}$  increases as vehicle speed  $V_A(t)$  increases.

Vehicle speed correction calculation map 583  
10 calculates a vehicle speed correction quantity  $V_{SUB}(t)$  which is employed to correct command vehicle speed  $V_{COM}(t)$  according to lateral-G  $Y_G(t)$ . Vehicle speed correction quantity  $V_{SUB}(t)$  is calculated by multiplying a correction coefficient CC determined  
15 from the lateral G and a predetermined variation limit of command vehicle speed  $V_{COM}(t)$ . In this embodiment, the predetermined variation limit of command vehicle speed  $V_{COM}(t)$  is set at  $0.021(\text{km/h/10ms})=0.06G$ . The predetermined variation  
20 limit of the command vehicle speed is equal to the maximum value of a variation (corresponding to acceleration/deceleration)  $\Delta V_{COM}(t)$  of the command vehicle speed shown in Fig. 6.

$$V_{SUB}(t) = CC \times 0.021 (\text{km/h/10ms}) \quad \text{---(5)}$$

25 As mentioned later, the vehicle speed correction quantity  $V_{SUB}(t)$  is added as a subtraction term in the calculation process of the command vehicle speed  $V_{COM}(t)$  which is employed to control the vehicle speed. Accordingly, command vehicle  
30 speed  $V_{COM}(t)$  is limited to a smaller value as vehicle correction quantity  $V_{SUB}(t)$  becomes larger.

Correction coefficient CC becomes larger as

lateral-G  $Y_G$  becomes larger, as shown in Fig. 4. The reason thereof is that the change of command vehicle speed  $V_{COM}(t)$  is limited more as the lateral-G becomes larger. However, when the lateral-G is smaller than or equal to  $0.1G$  as shown in Fig. 4, correction coefficient  $CC$  is set at zero since it is decided that it is not necessary to correct command vehicle speed  $V_{COM}(t)$ . Further, when the lateral-G is greater than or equal to  $0.3G$ , correction coefficient  $CC$  is set at a predetermined constant value. That is, the lateral-G never becomes greater than or equal to  $0.3G$  as far as the vehicle is operated under a usual driving condition. Therefore, in order to prevent the correction coefficient  $CC$  from being set at an excessively large value when the detection value of the lateral-G erroneously becomes large, the correction coefficient  $CC$  is set at such a constant value, such as at 2.

When a driver requests to increase the target vehicle speed by operating accelerate switch 40, that is, when acceleration of the vehicle is requested, the command vehicle speed  $V_{COM}(t)$  is calculated by adding present vehicle speed  $V_A(t)$  and command vehicle speed variation  $\Delta V_{COM}(t)$  and by subtracting vehicle speed correction quantity  $V_{SUB}(t)$  from the sum of present vehicle speed  $V_A(t)$  and command vehicle speed variation  $\Delta V_{COM}(t)$ .

Therefore, when command vehicle speed variation  $\Delta V_{COM}(t)$  is greater than vehicle speed correction quantity  $V_{SUB}(t)$ , the vehicle is accelerated. When command vehicle speed variation  $\Delta V_{COM}(t)$  is smaller than vehicle speed correction quantity  $V_{SUB}(t)$ , the vehicle is decelerated. Vehicle speed correction

quantity  $V_{SUB}(t)$  is obtained by multiplying the limit value of the command vehicle speed variation (a maximum value of the command vehicle speed variation) with correction coefficient CC shown in Fig. 4. Therefore, when the limit value of the command vehicle speed variation is equal to the command vehicle speed variation and when correction coefficient CC is 1, the amount for acceleration becomes equal to the amount for deceleration. In case of Fig. 4, when  $Y_G(t)=0.2$ , the amount for acceleration becomes equal to the amount for deceleration. Accordingly, the present vehicle speed is maintained when the correction coefficient CC is 1. In this example, when the lateral-G  $Y_G(t)$  is smaller than 0.2, the vehicle is accelerated. When the lateral-G  $Y_G(t)$  is larger than 0.2, the vehicle is decelerated.

When the driver requests to lower the target vehicle speed by operating coast switch 30, that is, when the deceleration of the vehicle is requested, the command vehicle speed  $V_{COM}(t)$  is calculated by subtracting command vehicle speed variation  $\Delta V_{COM}(t)$  and vehicle speed correction quantity  $V_{SUB}(t)$  from present vehicle speed  $V_A(t)$ . Therefore, in this case, the vehicle is always decelerated. The degree of the deceleration becomes larger as vehicle speed correction quantity  $V_{SUB}(t)$  becomes larger. That is, vehicle speed correction quantity  $V_{SUB}(t)$  increases according to the increase of the lateral-G  $Y_G(t)$ . The above-mentioned value 0.021(km/h/10ms) has been defined on the assumption that the vehicle is traveling on a highway.

As mentioned above, vehicle speed correction

quantity  $V_{SUB}(t)$  is obtained from the multiple  
between the correction coefficient CC according to  
the lateral acceleration and the limit value of the  
command vehicle speed variation  $V_{COM}(t)$ . Accordingly,  
5 the subtract term (vehicle speed correction  
quantity) increases according to the increase of the  
lateral acceleration so that the vehicle speed is  
controlled so as to suppress the lateral-G. However,  
as mentioned in the explanation of steer angle  
10 signal LPF block 581, the cutoff frequency  $f_c$  is  
lowered as the vehicle speed becomes larger.  
Therefore the time constant TSTR of the LPF is  
increased, and the steer angle LPF  $\theta_{LPF}(t)$  is  
decreased. Accordingly, the lateral acceleration  
15 estimated at the lateral-G calculating block 581 is  
also decreased. As a result, the vehicle speed  
correction quantity  $V_{SUB}(t)$ , which is obtained from  
the vehicle speed correction quantity calculation  
map 583, is decreased. Consequently, the steer  
20 angle becomes ineffective as to the correction of  
the command vehicle speed. In other words, the  
correction toward the decrease of the acceleration  
becomes smaller due to the decrease of vehicle speed  
correction quantity  $V_{SUB}(t)$ .

25 More specifically, the characteristic of the  
natural frequency  $\omega_{nSTR}$  relative to the steer angle is  
represented by the following equation (6).

$$\omega_{nSTR} = (2W / V_A) \sqrt{[Kf \cdot Kr \cdot (1 + A \cdot V_A^2) / m_v \cdot I]}$$

---(6)

30 In this equation (6),  $Kf$  is a cornering power of one  
front tire,  $Kr$  is a cornering power of one rear tire,  
 $W$  is a wheelbase dimension,  $m_v$  is a vehicle weight,  $A$

is a stability factor, and  $I$  is a vehicle yaw inertia moment.

The characteristic of the natural frequency  $\omega_{hSTR}$  performs such that the natural frequency  $\omega_{hSTR}$  becomes smaller and the vehicle responsibility relative to the steer angle degrades as the vehicle speed increases, and that the natural frequency  $\omega_{hSTR}$  becomes greater and the vehicle responsibility relative to the steer angle is improved as the vehicle speed decreases. That is, the lateral-G tends to be generated according to a steering operation as the vehicle speed becomes lower, and the lateral-G due to the steering operation tends to be suppressed as the vehicle speed becomes higher. Therefore, the vehicle speed control system according to the present invention is arranged to lower the responsibility by decreasing the cutoff frequency  $f_c$  according to the increase of the vehicle speed so that the command vehicle speed tends not to be affected by the correction due to the steer angle as the vehicle speed becomes higher.

A command vehicle speed variation determining block 590 receives vehicle speed  $V_A(t)$  and command vehicle speed maximum value  $V_{SMAX}$  and calculates the command vehicle speed variation  $\Delta V_{COM}(t)$  from the map shown in Fig. 6 on the basis of an absolute value  $|V_A - V_{SMAX}|$  of a deviation between the vehicle speed  $V_A(t)$  and the command vehicle speed maximum value  $V_{SMAX}$ .

The map for determining command vehicle speed variation  $\Delta V_{COM}(t)$  is arranged as shown in Fig. 6. More specifically, when absolute value  $|V_A - V_{SMAX}|$  of the deviation is within a range B in Fig. 6, the

vehicle is quickly accelerated or decelerated by increasing command vehicle speed variation  $\Delta V_{COM}(t)$  as the absolute value of the deviation between vehicle speed  $V_A(t)$  and command vehicle speed maximum value  $V_{SMAX}$  is increased within a range where command vehicle speed variation  $\Delta V_{COM}(t)$  is smaller than acceleration limit  $\alpha$  for deciding the stop of the vehicle speed control. Further, when the absolute value of the deviation is small within the range B in Fig. 6, command vehicle speed variation  $\Delta V_{COM}(t)$  is decreased as the absolute value of the deviation decreases within a range where the driver can feel an acceleration of the vehicle and the command vehicle speed variation  $\Delta V_{COM}(t)$  does not overshoot maximum value  $V_{SMAX}$  of the command vehicle speed. When the absolute value of the deviation is large and within a range A in Fig. 6, command vehicle speed variation  $\Delta V_{COM}(t)$  is set at a constant value which is smaller than acceleration limit  $\alpha$ , such as at 0.06G. When the absolute value of the deviation is small and within a range C in Fig. 6, command vehicle speed variation  $\Delta V_{COM}(t)$  is set at a constant value, such as at 0.03G.

Command vehicle speed variation determining block 590 monitors vehicle speed correction quantity  $V_{SUB}(t)$  outputted from lateral-G vehicle speed correction quantity calculating block 580, and decides that a traveling on a curved road is terminated when vehicle speed correction quantity  $V_{SUB}(t)$  is returned to zero after vehicle speed correction quantity  $V_{SUB}(t)$  took a value except for zero from zero. Further, command vehicle speed variation determining block 590 detects whether

vehicle speed  $V_A(t)$  becomes equal to maximum value  $V_{SMAX}$  of the command vehicle speed.

When it is decided that the traveling on a curved road is terminated, the command vehicle speed variation  $\Delta V_{COM}(t)$  is calculated from vehicle speed  $V_A(t)$  at the moment when it is decided that the traveling on a curved road is terminated, instead of determining the command vehicle speed variation  $\Delta V_{COM}(t)$  by using the map of Fig. 6 on the basis of the absolute value of a deviation between vehicle speed  $V_A(t)$  and maximum value  $V_{SMAX}$  of the command vehicle speed. The characteristic employed for calculating the command vehicle speed variation  $\Delta V_{COM}(t)$  under the curve-traveling terminated condition performs a tendency which is similar to that of Fig. 6. More specifically, in this characteristic employed in this curve terminated condition, a horizontal axis denotes vehicle speed  $V_A(t)$  instead of absolute value  $|V_A(t) - V_{SMAX}|$ . Accordingly, command vehicle speed variation  $\Delta V_{COM}(t)$  becomes small as vehicle speed  $V_A(t)$  becomes small. This processing is terminated when vehicle speed  $V_A(t)$  becomes equal to maximum value  $V_{SMAX}$  of the command vehicle speed.

Instead of the above determination method of command vehicle speed variation  $\Delta V_{COM}(t)$  at the termination of the curved road traveling, when vehicle speed correction quantity  $V_{SUB}(t)$  takes a value except for zero, it is decided that the curved road traveling is started. Under this situation, vehicle speed  $V_A(t_1)$  at a moment  $t_1$  of starting the curved road traveling may be previously stored, and command vehicle speed variation  $\Delta V_{COM}(t)$  may be

determined from a magnitude of a difference  $\Delta V_A$  between vehicle speed  $V_A(t_1)$  at the moment  $t_1$  of the start of the curved road traveling and vehicle speed  $V_A(t_2)$  at the moment  $t_2$  of the termination of the curved road traveling. The characteristic employed for calculating the command vehicle speed variation  $\Delta V_{COM}(t)$  under this condition performs a tendency which is opposite to that of Fig. 6. More specifically, in this characteristic curve, there is employed a map in which a horizontal axis denotes vehicle speed  $V_A(t)$  instead of  $|V_A(t) - V_{SMAX}|$ . Accordingly, command vehicle speed variation  $\Delta V_{COM}(t)$  becomes smaller as vehicle speed  $V_A(t)$  becomes larger. This processing is terminated when vehicle speed  $V_A(t)$  becomes equal to maximum value  $V_{SMAX}$  of the command vehicle speed.

That is, when the vehicle travels on a curved road, the command vehicle speed is corrected so that the lateral-G is suppressed within a predetermined range. Therefore, the vehicle speed is lowered in this situation generally. After the traveling on a curved road is terminated and the vehicle speed is decreased, the command vehicle speed variation  $\Delta V_{COM}(t)$  is varied according to vehicle speed  $V_A(t)$  at the moment of termination of the curved road traveling or according to the magnitude of the difference  $\Delta V_A$  between vehicle speed  $V_A(t_1)$  at the moment  $t_1$  of starting of the curved road traveling and vehicle speed  $V_A(t_2)$  at the moment  $t_2$  of the termination of the curved road traveling.

Further, when the vehicle speed during the curved road traveling is small or when vehicle speed difference  $\Delta V_A$  is small, command vehicle speed

variation  $\Delta V_{COM}(t)$  is set small and therefore the acceleration for the vehicle speed control due to the command vehicle speed is decreased. This operation functions to preventing a large acceleration from being generated by each curve when the vehicle travels on a winding road having continuous curves such as a S-shape curved road. Similarly, when the vehicle speed is high at the moment of the termination of the curved road traveling, or when vehicle speed difference  $\Delta V_A$  is small, it is decided that the traveling curve is single and command vehicle speed variation  $\Delta V_{COM}(t)$  is set at a large value. Accordingly, the vehicle is accelerated just after the traveling of a single curved road is terminated, and therefore the driver of the vehicle becomes free from a strange feeling due to the slow-down of the acceleration.

Command vehicle speed determining block 510 receives vehicle speed  $V_A(t)$ , vehicle speed correction quantity  $V_{SUB}(t)$ , command vehicle speed variation  $\Delta V_{COM}(t)$  and maximum value  $V_{SMAX}$  of the command vehicle speed and calculates command vehicle speed  $V_{COM}(t)$  as follows.

(a) When maximum value  $V_{SMAX}$  of the command vehicle speed is greater than vehicle speed  $V_A(t)$ , that is, when the driver requests accelerating the vehicle by operating accelerate switch 40 (or a resume switch), command vehicle speed  $V_{COM}(t)$  is calculated from the following equation (7).

$$V_{COM}(t) = \min[V_{SMAX}, V_A(t) + \Delta V_{COM}(t) - V_{SUB}(t)] \quad \text{---(7)}$$

That is, smaller one of maximum value  $V_{SMAX}$  and the value  $[V_A(t) + \Delta V_{COM}(t) - V_{SUB}(t)]$  is selected as command vehicle speed  $V_{COM}(t)$ .

(b) When  $V_{SMAX} = V_A(t)$ , that is, when the vehicle travels at a constant speed, command vehicle speed  $V_{COM}(t)$  is calculated from the following equation (8).

$$V_{COM}(t) = V_{SMAX} - V_{SUB}(t) \quad \text{---(8)}$$

5 That is, command vehicle speed  $V_{COM}(t)$  is obtained by subtracting vehicle speed correction quantity  $V_{SUB}(t)$  from maximum value  $V_{SMAX}$  of the command vehicle speed.

(c) When maximum value  $V_{SMAX}$  of the command vehicle speed is smaller than vehicle speed  $V_A(t)$ ,  
10 that is, when the driver requests to decelerate the vehicle by operating coast switch 30, command vehicle speed  $V_{COM}(t)$  is calculated from the following equation (9).

$$V_{COM}(t) = \max[V_{SMAX}, V_A(t) - \Delta V_{COM}(t) - V_{SUB}(t)] \quad \text{---(9)}$$

15 That is, larger one of maximum value  $V_{SMAX}$  and the value  $[V_A(t) - \Delta V_{COM}(t) - V_{SUB}(t)]$  is selected as command vehicle speed  $V_{COM}(t)$ .

Command vehicle speed  $V_{COM}(t)$  is determined from the above-mentioned manner, and the vehicle speed  
20 control system controls vehicle speed  $V_A(t)$  according to the determined command vehicle speed  $V_{COM}(t)$ .

A command drive torque calculating block 530 receives command vehicle speed  $V_{COM}(t)$  and vehicle speed  $V_A(t)$  and calculates a command drive torque  
25  $d_{FC}(t)$ . Fig. 7 shows a construction of command drive torque calculating block 530.

When the input is command vehicle speed  $V_{COM}(t)$  and the output is vehicle speed  $V_A(t)$ , a transfer characteristic (function)  $G_V(s)$  thereof is  
30 represented by the following equation (10).

$$G_V(s) = 1/(T_V \cdot s + 1) \cdot e^{(-L_V \cdot s)} \quad \text{---(10)}$$

In this equation (10),  $T_V$  is a first-order lag time

constant, and  $L_v$  is a dead time due to a delay of a power train system.

By modeling a vehicle model of a controlled system in a manner of treating command drive torque  $d_{FC}(t)$  as a control input (manipulated value) and vehicle speed  $V_A(t)$  as a controlled value, the behavior of a vehicle power train is represented by a simplified linear model shown by the following equation (11).

10 
$$V_A(t) = 1/(m_v \cdot R_t \cdot s) \cdot e^{(-L_v \cdot s)} \cdot d_{FC}(t) \text{ ---(11)}$$

In this equation (11),  $R_t$  is an effective (rotation) radius of a tire, and  $m_v$  is a vehicle mass (weight).

The vehicle model employing command drive torque  $d_{FC}(t)$  as an input and vehicle speed  $V_A(t)$  as an output performs an integral characteristic since the equation (11) of the vehicle model is of a  $1/s$  type.

Although the controlled system performs a non-linear characteristic which includes a dead time  $L_v$  due to the delay of the power train system and varies the dead time  $L_v$  according to the employed actuator and engine, the vehicle model employing the command drive torque  $d_{FC}(t)$  as an input and vehicle speed  $V_A(t)$  as an output can be represented by the equation (11) by means of the approximate zeroing method employing a disturbance estimator.

By corresponding the response characteristic of the controlled system of employing the command drive torque  $d_{FC}(t)$  as an input and vehicle speed  $V_A(t)$  as an output to a characteristic of the transfer function  $G_v(s)$  having a predetermined first-order lag  $T_v$  and the dead time  $L_v$ , the following relationship is obtained by using  $C_1(s)$ ,  $C_2(s)$  and  $C_3(s)$  shown in

Fig. 7.

$$C_1(s) = e^{(-L_v \cdot s)} / (T_H \cdot s + 1) \quad \text{---(12)}$$

$$C_2(s) = (m_v \cdot R_t \cdot s) / (T_H \cdot s + 1) \quad \text{---(13)}$$

$$d_v(t) = C_2(s) \cdot V_A(t) - C_1(s) \cdot d_{FC}(t) \quad \text{---(14)}$$

5 In these equations (12), (13) and (14),  $C_1(s)$  and  $C_2(s)$  are disturbance estimators for the approximate zeroing method and perform as a compensator for suppressing the influence due to the disturbance and modeling.

10 When a norm model  $G_v(s)$  is treated as a first-order low-pass filter having a time constant  $T_v$  upon neglecting the dead time of the controlled system, the model matching compensator  $C_3(s)$  takes a constant as follows.

$$15 \quad C_3(t) = m_v \cdot R_t / T_v \quad \text{---(15)}$$

From these compensators  $C_1(s)$ ,  $C_2(s)$  and  $C_3(s)$ , the command drive torque  $d_{FC}(t)$  is calculated from the following equation (16).

$$20 \quad d_{FC}(t) = C_3(s) \cdot \{V_{COM}(t) - V_A(t)\} - \{C_2(s) \cdot V_A(t) - C_1(s) \cdot d_{FC}(t)\} \quad \text{---(16)}$$

A drive torque of the vehicle is controlled on the basis of command drive torque  $d_{FC}(t)$ . More specifically, the command throttle opening is calculated so as to bring actual drive torque  $d_{FA}(t)$  closer to command drive torque  $d_{FC}(t)$  by using a map indicative of an engine non-linear stationary characteristic. This map is shown in Fig. 8, the relationship represented by this map has been previously measured and stored. Further, when the required torque is negative and is not ensured by the  
30 negative drive torque of the engine, the vehicle

control system operates the transmission and the brake system to ensure the required negative torque. Thus, by controlling the throttle opening, the transmission and the brake system, it becomes  
5 possible to modify the engine non-linear stationary characteristic into a linearized characteristic.

Since CVT 70 employed in this embodiment according to the present invention is provided with a torque converter with a lockup mechanism, vehicle  
10 speed control block 500 receives a lockup signal  $LU_s$  from a controller of CVT 70. The lockup signal  $LU_s$  indicates the lockup condition of CVT 70. When vehicle speed control block 500 decides that CVT is put in an un-lockup condition on the basis of the  
15 lockup signal  $LU_s$ , vehicle speed control block 500 increases the time constant  $T_H$  employed to represent the compensators  $C_1(s)$  and  $C_2(s)$  as shown in Fig. 7. The increase of the time constant  $T_H$  decreases the vehicle speed control feedback correction quantity  
20 (a correction coefficient for keeping a desired response characteristic). Therefore, it becomes possible to adjust the model characteristic to the response characteristic of the controlled system under the un-lockup condition, although the response  
25 characteristic of the controlled system under the un-lockup condition delays as compared with that of the controlled system under the lockup condition. Accordingly, the stability of the vehicle speed control system is ensured under both lockup  
30 condition and un-lockup condition.

Command drive torque calculating block 530 shown in Fig. 7 is constructed by compensators  $C_1(s)$  and  $C_2(s)$  for compensating the transfer

characteristic of the controlled system and compensator  $C_3(s)$  for achieving a response characteristic previously designed by a designer. Command drive torque calculating block 530 may be constructed by a pre-compensator  $C_F(s)$  for compensating so as to ensure a desired response characteristic determined by the designer, a norm model calculating block  $C_R(s)$  for calculating the desired response characteristic determined by the designer and a feedback compensator  $C_3(s)'$  for compensating a drift quantity (a difference between the target vehicle speed and the actual vehicle speed) with respect to the response characteristic of the norm model calculating section  $C_R(s)$ , as shown in Fig. 12.

The pre-compensator  $C_F(s)$  calculates a standard command drive torque  $d_{FC1}(t)$  by using the following filter in order to achieve the transfer function  $G_V(s)$  of the actual vehicle speed  $V_A(t)$  with respect to the command vehicle speed  $V_{COM}(t)$ .

$$D_{FC1}(t) = m_V \cdot R_T \cdot s \cdot V_{COM}(t) / (T_V \cdot s + 1) \quad \text{---(17)}$$

Norm model calculating block  $C_R(s)$  calculates a target response  $V_T(t)$  of the vehicle speed control system from the transfer function  $G_V(s)$  and the command vehicle speed  $V_{COM}(t)$  as follows.

$$V_T(t) = G_V(s) \cdot V_{COM}(t) \quad \text{---(18)}$$

Feedback compensator  $C_3(s)'$  calculates a correction quantity of the command drive torque so as to cancel a deviation when the deviation between the target response  $V_T(t)$  and the actual vehicle speed  $V_A(t)$  is caused. That is, the correction quantity  $d_v(t)'$  is calculated from the following

equation (19).

$$\dot{d}_v(t) = [(K_P \cdot s + K_I)/s][V_T(t) - V_A(t)] \quad \text{---(19)}$$

In this equation (19),  $K_P$  is a proportion control gain of the feedback compensator  $C_3(s)$ ,  $K_I$  is an  
5 integral control gain of the feedback compensator  $C_3(s)$ , and the correction quantity  $\dot{d}_v(t)$  of the drive torque corresponds to an estimated disturbance  $\dot{d}_v(t)$  explained in Fig. 7.

When it is decided that CVT 70 is put in the  
10 un-lockup condition from the lockup condition signal LUs, the correction quantity  $\dot{d}_v(t)$  is calculated from the following equation (20).

$$\dot{d}_v(t) = [(K_P' \cdot s + K_I')/s][V_T(t) - V_A(t)] \quad \text{---(20)}$$

In this equation (20),  $K_P' > K_P$ , and  $K_I' > K_I$ .  
15 Therefore, the feedback gain in the un-lockup condition of CVT 70 is decreased as compared with that in the lockup condition of CVT 70. Further, command drive torque  $\dot{d}_{FC}(t)$  is calculated from a standard command drive torque  $\dot{d}_{FC1}(t)$  and the  
20 correction quantity  $\dot{d}_v(t)$  as follows.

$$\dot{d}_{FC}(t) = \dot{d}_{FC1}(t) + \dot{d}_v(t) \quad \text{---(21)}$$

That is, when CVT 70 is put in the un-lockup condition, the feedback gain is set at a smaller value as compared with the feedback gain in the  
25 lockup condition. Accordingly, the changing rate of the correction quantity of the command drive torque becomes smaller, and therefore it becomes possible to adapt the response characteristic of the controlled system which characteristic delays under  
30 the un-lockup condition of CVT 70 as compared with the characteristic in the lockup condition. Consequently, the stability of the vehicle speed

control system is ensured under both lockup condition and un-lockup condition.

Next, the actuator drive system of Fig. 1 will be discussed hereinafter.

5        Command gear ratio calculating block 540 receives command drive torque  $d_{FC}(t)$ , vehicle speed  $V_A(t)$ , the output of coast switch 30 and the output of accelerator pedal sensor 90. Command gear ratio calculating block 540 calculates a command gear  
10        ratio  $DRATIO(t)$ , which is a ratio between an input rotation speed and an output rotation of CVT 70, on the basis of the received information and outputs command gear ratio  $DRATIO(t)$  to CVT 70 as mentioned later.

15        (a) When coast switch 30 is put in an off state, an estimated throttle opening  $TVO_{ESTI}$  is calculated from the throttle opening estimation map shown in Fig. 9 on the basis of vehicle speed  $V_A(t)$  and command drive torque  $d_{FC}(t)$ . Then, a command engine  
20        rotation speed  $N_{IN-COM}$  is calculated from the CVT shifting map shown in Fig. 10 on the basis of estimated throttle opening  $TVO_{ESTI}$  and vehicle speed  $V_A(t)$ . Further, command gear ratio  $DRATIO(t)$  is obtained from the following equation (22) on the  
25        basis of vehicle speed  $V_A(t)$  and command engine rotation speed  $N_{IN-COM}$ .

$$DRATIO(t) = N_{IN-COM} \cdot 2\pi \cdot Rt / [60 \cdot V_A(t) \cdot Gf]$$

---(22)

In this equation (22),  $Gf$  is a final gear ratio.

30        (b) When coast switch 30 is switched on, that is, when maximum value  $V_{SMAX}$  of the command vehicle speed is decreased by switching on coast switch 30, the previous value of command gear ratio

DRATIO(t-1) is maintained as the present command gear ratio DRATIO(t). Therefore, even when coast switch 30 is continuously switched on, command gear ratio DRATIO(t) is maintained at the value set just before the switching on of coast switch 30 until coast switch is switched off. That is, the shift down is prohibited for a period from the switching on of coast switch 30 to the switching off of coast switch 30.

That is, when the set speed of the vehicle speed control system is once decreased by operating coast switch 30 and is then increased by operating accelerate switch 40, the shift down is prohibited during this period. Therefore, even if the throttle opening is opened to accelerate the vehicle, the engine rotation speed is never radically increased under such a transmission condition. This prevents the engine from generating noises excessively.

An actual gear ratio calculating block 550 of Fig. 1 calculates an actual gear ratio RATIO(t) (an actual ratio between an input speed and an output speed of CVT 70) from the following equation on the basis of the engine rotation speed  $N_E(t)$  and vehicle speed  $V_A(t)$  which is obtained by detecting an engine spark signal through engine speed sensor 80.

$$RATIO(t) = N_E(t) / [V_A(t) \cdot G_f \cdot 2\pi \cdot R_t] \quad \text{---(23)}$$

A command engine torque calculating block 560 of Fig. 1 calculates a command engine torque  $TE_{COM}(t)$  from command drive torque  $d_{FC}(t)$ , actual gear ratio RATIO(t) and the following equation (24).

$$TE_{COM}(t) = d_{FC}(t) / [G_f \cdot RATIO(t)] \quad \text{---(24)}$$

A target throttle opening calculating block 570 of Fig. 1 calculates a target throttle opening  $TVO_{COM}$

from the engine performance map shown in Fig. 11 on the basis of command engine torque  $TE_{COM}(t)$  and engine rotation speed  $N_E(t)$ , and outputs the calculated target throttle opening  $TVO_{COM}$  to throttle actuator 60.

A command brake pressure calculating block 630 of Fig. 1 calculates an engine brake torque  $TE_{COM}'$  during a throttle full closed condition from the engine performance map shown in Fig. 11 on the basis of engine rotation speed  $N_E(t)$ . Further, command brake pressure calculating block 630 calculates a command brake pressure  $REF_{PBRK}(t)$  from the throttle full-close engine brake torque  $TE_{COM}'$ , command engine torque  $TE_{COM}(t)$  and the following equation (25).

$$REF_{PBRK}(t) = (TE_{COM} - TE_{COM}') \cdot Gm \cdot Gf / \{4 \cdot (2 \cdot AB \cdot RB \cdot \mu B)\} \quad \text{---(25)}$$

In this equation (25),  $Gm$  is a gear ratio of CVT 70,  $AB$  is a wheel cylinder force (cylinder pressure  $\times$  area),  $RB$  is an effective radius of a disc rotor, and  $\mu B$  is a pad friction coefficient.

Next, the suspending process of the vehicle speed control will be discussed hereinafter.

A vehicle speed control suspension deciding block 620 of Fig. 1 receives an accelerator control input  $APO$  detected by accelerator pedal sensor 90 and compares accelerator control input  $APO$  with a predetermined value. The predetermined value is an accelerator control input  $APO_1$  corresponding to a target throttle opening  $TVO_{COM}$  inputted from a target throttle opening calculating block 570, that is a throttle opening corresponding to the vehicle speed automatically controlled at this moment. When accelerator control input  $APO$  is greater than a

predetermined value, that is, when a throttle opening becomes greater than a throttle opening controlled by throttle actuator 60 due to the accelerator pedal depressing operation of the drive,  
5 vehicle speed control suspension deciding block 620 outputs a vehicle speed control suspending signal.

Command drive torque calculating block 530 and target throttle opening calculating block 570 initialize the calculations, respectively in reply  
10 to the vehicle speed control suspending signal, and the transmission controller of CVT 70 switches the shift-map from a constant speed traveling shift-map to a normal traveling shift map. That is, the vehicle speed control system according to the  
15 present invention suspends the constant speed traveling, and starts the normal traveling according to the accelerator pedal operation of the driver.

The transmission controller of CVT 70 has stored the normal traveling shift map and the  
20 constant speed traveling shift map, and when the vehicle speed control system according to the present invention decides to suspend the constant vehicle speed control, the vehicle speed control system commands the transmission controller of CVT  
25 70 to switch the shift map from the constant speed traveling shift map to the normal traveling shift map. The normal traveling shift map has a high responsibility characteristic so that the shift down is quickly executed during the acceleration. The  
30 constant speed traveling shift map has a mild characteristic which impresses a smooth and mild feeling to a driver when the shift map is switched from the constant speed traveling mode to the normal

traveling mode.

Vehicle speed control suspension deciding block 620 stops outputting the vehicle speed control suspending signal when the accelerator control input APO returns to a value smaller than the predetermined value. Further, when the accelerator control input APO is smaller than the predetermined value and when vehicle speed  $V_A(t)$  is greater than the maximum value  $V_{SMAX}$  of the command vehicle speed, vehicle speed control suspension deciding block 620 outputs the deceleration command to the command drive torque calculating block 530.

When the output of the vehicle speed control suspending signal is stopped and when the deceleration command is outputted, command drive torque calculating block 530 basically executes the deceleration control according to the throttle opening calculated at target throttle opening calculating block 570 so as to achieve command drive torque  $d_{FC}(t)$ . However, when command drive torque  $d_{FC}(t)$  cannot be achieved only by fully closing the throttle, the transmission control is further employed in addition to the throttle control. More specifically, in such a large deceleration force required condition, command gear ratio calculating block 540 outputs the command gear ratio DRATIO (shift down command) regardless the road gradient, such as traveling on a down slope or a flat road. CVT 70 executes the shift down control according to the command gear ratio DRATIO to supply the shortage of the decelerating force.

Further, when command drive torque  $d_{FC}(t)$  is not ensured by both the throttle control and the

transmission control, and when the vehicle travels on a flat road, the shortage of command drive torque  $d_{FC}(t)$  is supplied by employing the brake system. However, when the vehicle travels on a down slop, the braking control by the brake system is prohibited by outputting a brake control prohibiting signal BP from command drive torque calculating block 530 to a command brake pressure calculating block 630. The reason for prohibiting the braking control of the brake system on the down slop is as follows.

If the vehicle on the down slope is decelerated by means of the brake system, it is necessary to continuously execute the braking. This continuous braking may cause the brake fade. Therefore, in order to prevent the brake fade, the vehicle speed control system according to the present invention is arranged to execute the deceleration of the vehicle by means of the throttle control and the transmission control without employing the brake system when the vehicle travels on a down slope.

With the thus arranged suspending method, even when the constant vehicle speed cruise control is restarted after the constant vehicle speed cruise control is suspended in response to the temporal acceleration caused by depressing the accelerator pedal, a larger deceleration as compared with that only by the throttle control is ensured by the down shift of the transmission. Therefore, the conversion time period to the target vehicle speed is further shortened. Further, by employing a continuously variable transmission (CVT 70) for the deceleration, a shift shock is prevented even when

the vehicle travels on the down slope. Further, since the deceleration ensured by the transmission control and the throttle control is larger than that only by the throttle control and since the

5 transmission control and the throttle control are executed to smoothly achieve the drive torque on the basis of the command vehicle speed variation  $\Delta V_{COM}$ , it is possible to smoothly decelerate the vehicle while keeping the deceleration degree at the

10 predetermined value. In contrast to this, if a normal non-CVT automatic transmission is employed, a shift shock is generated during the shift down, and therefore even when the larger deceleration is requested, the conventional system employed a

15 non-CVT transmission has executed only the throttle control and has not executed the shift down control of the transmission.

By employing a continuously variable transmission (CVT) with the vehicle speed control

20 system, it becomes possible to smoothly shift down the gear ratio of the transmission. Therefore, when the vehicle is decelerated for continuing the vehicle speed control, a deceleration greater than that only by the throttle control is smoothly

25 executed.

Next, a stopping process of the vehicle speed control will be discussed.

A drive wheel acceleration calculating block 600 of Fig. 1 receives vehicle speed  $V_A(t)$  and

30 calculates a drive wheel acceleration  $\alpha_{OBS}(t)$  from the following equation (26).

$$\alpha_{OBS}(t) = [K_{OBS} \cdot s / (T_{OBS} \cdot s^2 + s + K_{OBS})] \cdot V_A(t)$$

---(26)

In this equation (26),  $K_{OBS}$  is a constant, and  $T_{OBS}$  is a time constant.

Since vehicle speed  $V_A(t)$  is a value calculated from the rotation speed of a tire (drive wheel), the value of vehicle speed  $V_A(t)$  corresponds to the rotation speed of the drive wheel. Accordingly, drive wheel acceleration  $\alpha_{OBS}(t)$  is a variation (drive wheel acceleration) of the vehicle speed obtained from the drive wheel speed  $V_A(t)$ .

Vehicle speed control stop deciding block 610 compares drive wheel acceleration  $\alpha_{OBS}(t)$  calculated at drive torque calculating block 600 with the predetermined acceleration limit  $\alpha$  which corresponds to the variation of the vehicle speed, such as 0.2G. When drive wheel acceleration  $\alpha_{OBS}(t)$  becomes greater than the acceleration limit  $\alpha$ , vehicle speed control stop deciding block 610 outputs the vehicle speed control stopping signal to command drive torque calculating block 530 and target throttle opening calculating block 570. In reply to the vehicle speed control stopping signal, command drive torque calculating block 530 and target throttle opening calculating block 570 initialize the calculations thereof respectively. Further, when the vehicle speed control is once stopped, the vehicle speed control is not started until set switch 20 is again switched on.

Since the vehicle speed control system shown in Fig. 1 controls the vehicle speed at the command vehicle speed based on command vehicle speed variation  $\Delta V_{COM}$  determined at command vehicle speed variation determining block 590. Therefore, when the vehicle is normally controlled, the vehicle

speed variation never becomes greater than the limit of the command vehicle speed variation, for example,  $0.06G = 0.021(\text{km/h}/10\text{ms})$ . Accordingly, when drive wheel acceleration  $\alpha_{\text{OBS}}(t)$  becomes greater than the  
5 predetermined acceleration limit  $\alpha$  which corresponds to the limit of the command vehicle speed acceleration, there is a possibility that the drive wheels are slipping. That is, by comparing drive wheel acceleration  $\alpha_{\text{OBS}}(t)$  with the predetermined  
10 acceleration limit  $\alpha$ , it is possible to detect the generation of slippage of the vehicle. Accordingly, it becomes possible to execute the slip decision and the stop decision of the vehicle speed control, by obtaining drive wheel acceleration  $\alpha_{\text{OBS}}(t)$  from the  
15 output of the normal vehicle speed sensor without providing an acceleration sensor in a slip suppressing system such as TCS (traction control system) and without detecting a difference between a rotation speed of the drive wheel and a rotation  
20 speed of a driven wheel. Further, by increasing the command vehicle speed variation  $\Delta V_{\text{COM}}$ , it is possible to improve the responsibility of the system to the target vehicle speed.

Although the embodiment according to the  
25 present invention has been shown and described such that the stop decision of the vehicle speed control is executed on the basis of the comparison between the drive wheel acceleration  $\alpha_{\text{OBS}}(t)$  and the predetermined value, the invention is not limited to  
30 this and may be arranged such that the stop decision is made when a difference between the command vehicle variation  $\Delta V_{\text{COM}}$  and drive wheel acceleration  $\alpha_{\text{OBS}}(t)$  becomes greater than a predetermined value.

Command vehicle speed determining block 510 of Fig. 1 decides whether  $V_{SMAX} < V_A$ , that is, whether the command vehicle speed  $V_{COM}(t)$  is greater than vehicle speed  $V_A(t)$  and is varied to the decelerating direction. Command vehicle speed determining block 510 sets command vehicle speed  $V_{COM}(t)$  at vehicle speed  $V_A(t)$  or a predetermined vehicle speed smaller than vehicle speed  $V_A(t)$ , such as at a value obtained by subtracting 5km/h from vehicle speed  $V_A(t)$ , and sets the initial values of integrators  $C_2(s)$  and  $C_1(s)$  at vehicle speed  $V_A(t)$  so as to set the output of the equation  $C_2(s) \cdot V_A(t) - C_1(s) \cdot d_{FC}(t) = d_v(t)$  at zero. As a result of this settings, the outputs of  $C_1(s)$  and  $C_2(s)$  become  $V_A(t)$  and therefore the estimated disturbance  $d_v(t)$  becomes zero. Further, this control is executed when the variation  $\Delta V_{COM}$  which is a changing rate of command vehicle speed  $V_{COM}$  is greater in the deceleration direction than the predetermined deceleration, such as 0.06G. With this arrangement, it becomes possible to facilitate unnecessary initialization of the command vehicle speed ( $V_A(t) \rightarrow V_{COM}(t)$ ) and initialization of the integrators, and to decrease the shock due to the deceleration.

Further, when the command vehicle speed (command control value at each time until the actual vehicle speed reaches the target vehicle speed) is greater than the actual vehicle speed and when the time variation (change rate) of the command vehicle speed is turned to the decelerating direction, by changing the command vehicle speed to the actual vehicle speed or the predetermined speed smaller than the actual vehicle speed, the actual vehicle

speed is quickly converged into the target vehicle speed. Furthermore, it is possible to keep the continuing performance of the control by initializing the calculation of command drive torque  
5 calculating block 530 from employing the actual vehicle speed or a speed smaller than the actual vehicle speed.

Further, if the vehicle speed control system is arranged to execute a control for bringing an actual  
10 inter-vehicle distance closer to a target inter-vehicle distance so as to execute a vehicle traveling while keeping a target inter-vehicle distance set by a driver with respect to a preceding vehicle, the vehicle speed control system is  
15 arranged to set the command vehicle speed so as to keep the target inter-vehicle distance. In this situation, when the actual inter-vehicle distance is lower than a predetermined distance and when the command vehicle speed variation  $\Delta V_{COM}$  is greater than  
20 the predetermined value (0.06G) in the deceleration direction, the change ( $V_A \rightarrow V_{COM}$ ) of the command vehicle speed  $V_{COM}$  and the initialization of command drive torque calculating block 530 (particularly, integrator) are executed. With this arrangement, it  
25 becomes possible to quickly converge the inter-vehicle distance to the target inter-vehicle distance. Accordingly, the excessive approach to the preceding vehicle is prevented, and the continuity of the control is maintained. Further,  
30 the decrease of the unnecessary initialization ( $V_A(t) \rightarrow V_{COM}(t)$  and initialization of integrators) decreases the generation of the shift down shock.
